Which of the following extra-intestinal manifestations of inflammatory bowel disease follows disease activity?

- A. Pyoderma gangrenosum
- B. Uveitis
- C. Episcleritis
- D. Ankylosing spondylitis
- E. Primary sclerosing cholangitis

**Answer: C**

Certain EIM such as pauciarticular arthritis, oral aphthous ulcers, erythema nodosum, or episcleritis usually occur with increased intestinal disease activity. Other EIM such as ankylosing spondylitis and uveitis usually follow an independent course from IBD disease activity. And finally, some EIM such as PSC and pyoderma gangrenosum may or may not be related to IBD disease activity.
